

Day 6 – Task 2: CSS Position Practical

1. Introduction

Today, I worked on a practical task based on the CSS position property. The objective was to understand how different position values can be used to arrange elements at specific locations on a webpage. I created multiple boxes and applied various position properties to observe their behaviour.

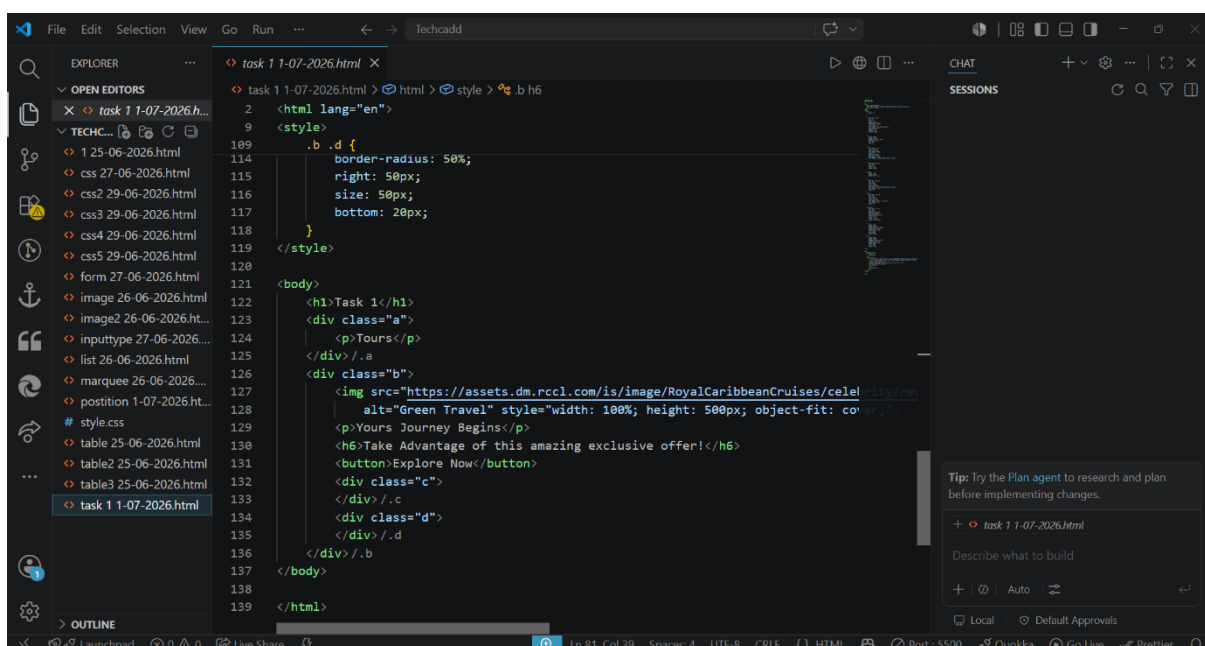

2. Practical Task

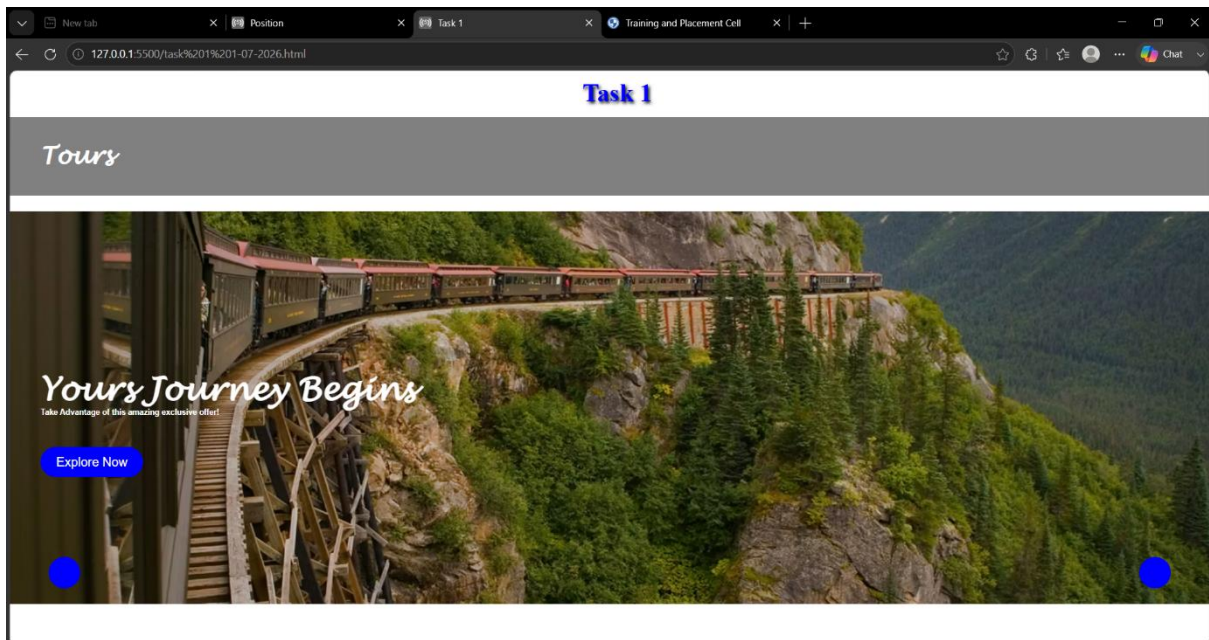

In this task, I designed a webpage containing multiple-coloured boxes. I used different CSS position values such as relative, absolute, fixed, and sticky to place the boxes at different locations. I also used the top, right, bottom, and left properties to control the exact position of each element.

During the task, I observed that:

- relative moves an element from its original position.
- absolute positions an element relative to its parent.
- fixed keeps an element fixed on the screen while scrolling.
- sticky behaves like a relative element until a specific scroll position is reached.

3. Example

Conclusion

Today, I successfully completed the second practical task on the CSS position property. I learned how to position elements accurately using different position values and coordinate properties such as top, bottom, left, and right. This practical session improved my understanding of webpage layouts and helped me build more structured and responsive web designs.
